DESIGN AND METHODOLOGY

Title: - The Limit

Architecture of the proposed model: -

A task management application typically consists of several components, including a front-end user interface, a back-end server, and a database for storing tasks and user information. The overall architecture of the application can vary depending on the specific requirements and technologies used, but a basic architecture might look something like this:

User interface: The front-end user interface is the part of the application that users interact with. It could be a mobile app or a web app, and it would typically include features such as task lists, due dates, reminders, and notifications. The user interface is built using technologies such as HTML, CSS, and JavaScript.

Server: The back-end server is responsible for processing requests from the user interface and communicating with the database to retrieve and store data. The server could be built using a variety of technologies, such as Node.js, Ruby on Rails, or Python Flask.

Database: The database stores all the tasks and user information for the application. Depending on the size and complexity of the application, a relational database such as MySQL or PostgreSQL may be used, or a NoSQL database such as MongoDB or Firebase.

APIs: The front-end and server communicate with each other using APIs (Application Programming Interfaces). The APIs define the format of requests and responses between the two components, and they can be built using RESTful architecture or GraphQL.

Authentication and authorization: To ensure that only authorized users can access the application, the server typically includes an authentication system such as OAuth, JWT or session-based authentication. It is important to protect the user's information as well, like hashing passwords.

Overall, the architecture of a task management application is focused on providing a user-friendly interface, with an efficient server to manage and store the data, and effective and secure authentication and authorization measures to protect the user's data.

Detail Explanation of Model: -

We decided to develop a reminder Web Based application called **The Limit**

The solution to the problem statement of "A task management application that allows users to create and track tasks, set reminders, and collaborate with others" would be to develop a web-based or mobile application that has the following features:

Task creation: Users can easily create tasks with detailed descriptions and set due dates.

Task tracking: Users can track the progress of tasks and view the status of tasks assigned to them or others.

Reminders: Users can set reminders for tasks to ensure they stay on track and meet deadlines.

Collaboration: Users can share tasks and collaborate with others in real-time, allowing for seamless communication and teamwork.

Customization: Users can customize the interface and settings to fit their personal preferences and workflow.

Accessibility: The application should be accessible from any device, allowing users to manage their tasks from anywhere.

Integrations: Integrating the application with other productivity tools like calendar, email, messaging apps will make it more convenient for the users.

Reporting and Analytics: Users should be able to generate reports and see analytics of their progress, or their team's progress.

Overall, the application should be designed to simplify the task management process and increase productivity and accountability within teams and individuals.
